ABSTRACT

In this paper a low cost, simple and small size ultrawideband circular monopole antenna is designed. The notch band is created by multiple number of slots in the ground plane. The proposed antenna is designed on the FR-4 substrate of height 1.6 mm. The antenna is designed with ground plane of dimension 50 x 55 mm and is fed by 50 ohm microstrip line. It is found that the EBG design approach in the ground plane is a good candidate for frequency rejection of wide range. The antenna achieves an operational bandwidth of 1.5 Ghz (1.5 Ghz to 3 Ghz) which included ISM band (1.8 and 2.4 Ghz), WiFi / Bluetooth (2.4 Ghz), Satellite Radio (2.3 Ghz), and GPS (1.575 Ghz).

Keywords: Wireless Network, Hospital, Mobile Devices.

1 INTRODUCTION

Ultra wide band system have become more promising since they have low power consumption, low cost and capability of high data rate, low interference and low cost of installation when required for so many short range applications. Printed monopole antenna fabricated on substrate with modified ground plane provides large impedance bandwidth, which is useful for designing UWB microstrip antennas. In addition to UWB, Bluetooth applications have the advantage of license free applications in the ISM Band, which includes industrial, scientific and medical (2.4 - 2.484 Ghz band). Bluetooth is also one of the application, which used to transfer data between portable devices with high data rate [1].

Various methods have been proposed for Wideband characteristics. The conventional methods are cutting slots on the patch / ground plane or putting parasitic elements near to the radiator. Usually one notch or one slot is adequate for a notch band. The limitation of one notch is that they reject only one band. Due to the limitations of single-notch UWB antennas there is motivation to design dual / multinothech ultra wideband antennas. for multinothch / wide band multielements are commonly needed [3].

Recently Electromagnetic Band Gap (EBG) structure have been introduced and various types of EBG structures have been implemented in different applications such as reduction of surface waves, reduction of mutual coupling between two planer antennas. Since an EBG structure has a filtering behavior, it can be used to design UWB antennas with stop band characteristics [4].

The paper starts with the design of simple monopole antenna. The mushroom like EBG structure have been used in the same plane of monopole antenna for wide band response. The ground plane of antenna is designed with four rectangular slots of different length and width. The antenna radiates over the frequency band from 1.5 Ghz to 3 Ghz, which include different applications like ISM Band (industrial, scientific and medical applications), WiFi and Bluetooth, Cell phones, GPS, Microwave Oven and Satellite Radio.

The detail of antenna design with ultrawideband characteristics are given in the following sections.
2 ESIGN AND IMPLEMENTATION

2.1 EBG Structure

The mushroom like EBG structure which we have studied before that it can provide a band gap characteristics. The EBG structure which we have used here is planer type of structure, which is based on usual mushroom type EBG structure. The difference between mushroom-like EBG structure and planer type of EBG structure is that in mushroom-like EBG structure there is a vias connecting patch to the ground plane, whereas in the planer type there is no connection i.e. no vias is connected.

It uses 1.6 mm thick FR-4 as a substrate. The metallic pattern i.e EBG structure is formed on the same plane, where antenna is designed while the other side metallic ground plane is designed. The structure does not used any vias to connect the patches with the ground plane, which makes the design simple and easy in fabrication. The unit cell dimension is 21.7mm x 17mm , which is shown below in Figure 1.

![Fig. 1. unit cell of EBG structure](image)

2.2 UWB Monopole Antenna with Defected Ground Plane

The configuration of proposed antenna is shown in Figure 2. The antenna is circular monopole antenna with defected ground plane. The antenna is the basic unit of our structure, which is attached to the EBG structure on the same plane. The antenna is fabricated on FR-4 substrate of thickness 1.6 mm and the relative permittivity of 4.4. The width of a 50-Ω microstrip feed line is 4 mm. The size of the antenna is 50mmx 55mm.

The geometry of the circular monopole antenna with two cell of EBG structure along the feed line is shown in Figure 3.

![Fig. 2. Geometry of monopole antenna with EBG structure](image)

This antenna will be combined with a ground plane, which contain four rectangular slots. The structure of ground plane is shown in figure-3. The ground plane dimension is 50mm x 55 mm.

The parameters of ground plane slots, the outer most first slot dimension is 50 mm x 45 mm, the second slot 40mm x 30mm, the third slot 23mm x 20mm and the inner most slot is 11mm x 10mm , which is shown below.

![Fig. 3. geometry of ground plane with rectangular slots](image)

The fabricated view of monopole antenna is shown in figure 4 and 5. The fabrication is done, so that we can see the effect of environment and other parameters on the measurements.
3 RESULTS AND DISCUSSION

The measured return loss characteristics of the fabricated monopole antenna has been shown in Figure 6. The results shows the ultra wide band response. The -10 dB return loss is for 1.5 Ghz frequency band (1.5 Ghz to 3 Ghz), which means the -10 dB bandwidth of the monopole antenna, which we have fabricated is 1.5 Ghz, this is because we named it UWB monopole antenna. The wide stop band is created due to EBG structure and defected ground plane. The peak (negative) value of return loss is for 1.62 Ghz, which is -48 dB.

The proposed monopole antenna with EBG structure and defected ground plane has been designed and optimized by CST microwave studio. CST microwave studio is used for calculating various parameters of antenna such as gain, Directivity, efficiency etc.

First we will discuss about the gain of the antenna. The gain of the monopole antenna is simulated using the far field pattern. The gain is calculated for the band from 1.5 Ghz to 3 Ghz, in which the gain is calculated for different frequencies. The maximum gain is achieved at frequency 1.62 Ghz, which is 4.628 dB and minimum is at 2.1 Ghz, which is -2.69 dB. So the gain variation is 7.318 dB.

The variation of gain over the 1.5 Ghz band (1.5 to 3 Ghz) is shown in figure-7.
Now we will analyse how the directivity of the antenna varies over the frequency band of 1.5 Ghz. Figure-8 shows the simulated directivity of monopole antenna. The directivity of the antenna is 6.989 dBi at the frequency 2.8 Ghz and minimum at 2.1 Ghz, which is 3.77 Ghz.

![Graph showing variation of Directivity over the frequency band](image1)

Fig. 8. variation of Directivity over the frequency band

Now we will characterized the efficiency of the monopole antenna. The efficiency of the antenna determines which band is much suitable for practical applications. The maximum frequency comes about 90 % for 1.62 Ghz. The efficiency graph of monopole antenna is shown in figure-9.

![Graph showing Efficiency of monopole antenna](image2)

Fig. 9. Efficiency of monopole antenna

From all of the above results we can determine that between the 1.5 Ghz to 3 Ghz the best results for various parameters is 1.62 Ghz and the gain and directivity shows its lowest value at 2.1 Ghz. So now we will determine the radiation pattern and polar plot for 1.62 Ghz and 2.1 Ghz, so that we can compare the far field results, which is shown below.

6 CONCLUSION

In this paper an approach to design the UWB antenna has been proposed. The design is simply placing the planer EBG structure near to the feed line of monopole antenna for create band gap also the ground plane is consisting of multiple number of slots for creating multiple number of notch band which increase the overall bandwidth of antenna. Implementing the EBG structure in the vicinity of feed line does not change the behavior of radiating element and this is the advantage of proposed method. From the simulation results it can be concluded that the introduction of EBG structure has negligible effect on the various parameters of patch antenna. Therefore the proposed antenna is a good candidate for UWB applications including WLAN, Bluetooth, GPS and ISM band.
